

Internal energy

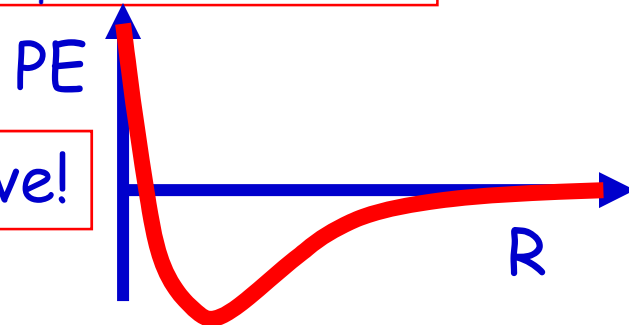

The **internal** (total) energy for an **ideal gas** is the total kinetic energy of the atoms/particles in a gas.

For a non-ideal gas: the internal energy is due to kinetic and potential energy associated with:

- translational motion
- rotational motion
- vibrational motion
- intermolecular potential energy

$$|PE_{\text{ideal gas}}=0| < |PE_{\text{non-ideal gas}}| < |PE_{\text{liquid}}| < |PE_{\text{solid}}|$$

PE: negative!

Heat

Heat: The transfer of energy between objects because their temperatures are different.

Heat: energy transfer Symbol: Q

Units: Calorie (cal) or Joule (J)
1 cal = 4.186 J (energy needed to raise
1 g of water by 1 °C)

Heat transfer to an object

The amount of energy transfer Q to an object with mass m when its temperature is raised by ΔT :

Example

A 1 kg block of Copper is raised in temperature by 10 °C. What was the heat transfer Q.?

Answer:

$$Q = cm\Delta T$$

$$= 387 * 1 * 10 = 3870 \text{ J}$$

$$1 \text{ cal} = 4.186 \text{ J}$$

$$Q = 924.5 \text{ cal}$$

TABLE 11.1

Specific Heats of Some Materials at Atmospheric Pressure

| Substance | J/kg · °C | cal/g · °C |
|-----------|-----------|------------|
| Aluminum | 900 | 0.215 |
| Beryllium | 1 820 | 0.436 |
| Cadmium | 230 | 0.055 |
| Copper | 387 | 0.092 4 |
| Germanium | 322 | 0.077 |
| Glass | 837 | 0.200 |
| Gold | 129 | 0.030 8 |
| Ice | 2 090 | 0.500 |
| Iron | 448 | 0.107 |
| Lead | 128 | 0.030 5 |
| Mercury | 138 | 0.033 |
| Silicon | 703 | 0.168 |
| Silver | 234 | 0.056 |
| Steam | 2 010 | 0.480 |
| Water | 4 186 | 1.00 |

Another one

A block of Copper is dropped from a height of 10 m. Assuming that all the potential energy is transferred into internal energy (heat) when it hits the ground, what is the raise in temperature of the block ($c_{\text{copper}}=387 \text{ J}/(\text{kg } ^\circ\text{C})$)?

Potential energy: $mgh=10 \text{ mg J}$

All transferred into heat Q: $Q = cm\Delta T$

$$10mg = 387m\Delta T$$

$$\Delta T = 10 \text{ g}/387 = 0.25 \text{ } ^\circ\text{C}$$

Calorimetry

If we connect two objects with different temperature energy will be transferred from the hotter to the cooler one until their temperatures are the same.

If the system is isolated:

$$m_{\text{cold}}c_{\text{cold}}(T_{\text{final}} - T_{\text{cold}}) = -m_{\text{hot}}c_{\text{hot}}(T_{\text{final}} - T_{\text{hot}})$$

$Q_{\text{cold}} = -Q_{\text{hot}}$

the final temperature is: $T_{\text{final}} = \frac{m_{\text{cold}}c_{\text{cold}}T_{\text{cold}} + m_{\text{hot}}c_{\text{hot}}T_{\text{hot}}}{m_{\text{cold}}c_{\text{cold}} + m_{\text{hot}}c_{\text{hot}}}$

An example

The contents of a can of soda (0.33 kg) which is cooled to 4 °C is poured into a glass (0.1 kg) that is at room temperature (20 °C). What will the temperature of the filled glass be after it has reached full equilibrium (glass and liquid have the same temperature)?

Given $c_{\text{water}}=4186 \text{ J}/(\text{kg } ^\circ\text{C})$ and $c_{\text{glass}}=837 \text{ J}/(\text{kg } ^\circ\text{C})$

$$Q_{\text{cold}} = -Q_{\text{hot}}$$
$$m_{\text{water}}c_{\text{water}}(T_{\text{final}} - T_{\text{water}}) = -m_{\text{glass}}c_{\text{glass}}(T_{\text{final}} - T_{\text{glass}})$$
$$T_{\text{final}} = \frac{m_{\text{water}}c_{\text{water}}T_{\text{water}} + m_{\text{glass}}c_{\text{glass}}T_{\text{glass}}}{m_{\text{water}}c_{\text{water}} + m_{\text{glass}}c_{\text{glass}}}$$

$$= (0.33 * 4186 * 4 + 0.1 * 837 * 20) / (0.33 * 4186 + 0.1 * 837) =$$
$$= 4.9 \text{ } ^\circ\text{C}$$

And another

A block of unknown substance with a mass of 8 kg, initially at $T=280$ K is thermally connect to a block of copper (5 kg) that is at $T=320$ K ($c_{\text{copper}}=0.093$ cal/g $^{\circ}\text{C}$). After the system has reached thermal equilibrium the temperature T equals 290 K. What is the specific heat of the unknown material in cal/g $^{\circ}\text{C}$?

$$Q_{\text{cold}} = -Q_{\text{hot}}$$

$$m_{\text{unknown}} c_{\text{unknown}} (T_{\text{final}} - T_{\text{unknown}}) = -m_{\text{copper}} c_{\text{copper}} (T_{\text{final}} - T_{\text{copper}})$$

$$c_{\text{unknown}} = \frac{-m_{\text{copper}} c_{\text{copper}} (T_{\text{final}} - T_{\text{copper}})}{m_{\text{unknown}} (T_{\text{final}} - T_{\text{unknown}})}$$

$$c_{\text{unkown}} = \frac{-5000 \cdot 0.093 \cdot (290 - 320)}{8000 \cdot (290 - 280)} = 0.17 \text{ cal/g } ^{\circ}\text{C}$$

Heating water with a ball of Lead

A ball of Lead at $T=100\text{ }^{\circ}\text{C}$ with mass 300 g is dropped in a glass of water (0.3 L) at $T=20\text{ }^{\circ}\text{C}$. What is the final (after thermal equilibrium has occurred) temperature of the system? ($c_{\text{water}}=1\text{ cal/g }^{\circ}\text{C}$, $c_{\text{lead}}=0.03\text{ cal/g }^{\circ}\text{C}$ $\rho_{\text{water}}=10^3\text{ kg/m}^3$)

$$Q_{\text{cold}} = -Q_{\text{hot}}$$
$$m_{\text{water}}c_{\text{water}}(T_{\text{final}} - T_{\text{water}}) = -m_{\text{lead}}c_{\text{lead}}(T_{\text{final}} - T_{\text{lead}})$$
$$T_{\text{final}} = \frac{m_{\text{water}}c_{\text{water}}T_{\text{water}} + m_{\text{lead}}c_{\text{lead}}T_{\text{lead}}}{m_{\text{water}}c_{\text{water}} + m_{\text{lead}}c_{\text{lead}}}$$

$$= (0.3 \cdot 1 \cdot 20 + 0.3 \cdot 0.03 \cdot 100) / (0.3 \cdot 1 + 0.3 \cdot 0.03) =$$
$$= 6.9 / 0.309 = 22.3^{\circ}\text{C}$$

Phase Change

Gas ↔
liquid

Phase change

When heat is added to a liquid, potential energy goes to 0
(the energy stored in the stickiness of the liquid is taken away)

DURING THE CHANGE FROM LIQUID TO GAS, THE KINETIC ENERGY DOES NOT CHANGE AND SO THE TEMPERATURE DOES NOT CHANGE.

ALL ADDED HEAT GOES TO CHANGING PE

When heat is taken from a gas, potential energy goes to the stickiness of the fluid

DURING THE CHANGE FROM GAS TO LIQUID, THE KINETIC ENERGY DOES NOT CHANGE AND SO THE TEMPERATURE DOES NOT CHANGE.

ALL REMOVED HEAT GOES TO CHANGING PE

liquid ↔
solid

Phase change

When heat is added to a solid to make a liquid, potential energy in the bonds between the atoms become smaller

DURING THE CHANGE FROM SOLID TO LIQUID, THE KINETIC ENERGY DOES NOT CHANGE AND SO THE TEMPERATURE DOES NOT CHANGE.

ALL ADDED HEAT GOES TO CHANGING PE

When heat is taken from a liquid, the bonds between atoms becomes stronger (potential energy is more negative)

DURING THE CHANGE FROM LIQUID TO SOLID, THE KINETIC ENERGY DOES NOT CHANGE AND SO THE TEMPERATURE DOES NOT CHANGE.

ALL REMOVED HEAT GOES TO CHANGING PE

Okay, the Temperature does not change in a phase transition!

But what is the amount of heat added to make the phase transition?

$$Q_{\text{gas} \rightarrow \text{liquid}} = -ML_v \quad M: \text{mass}$$
$$Q_{\text{liquid} \rightarrow \text{gas}} = +ML_v$$

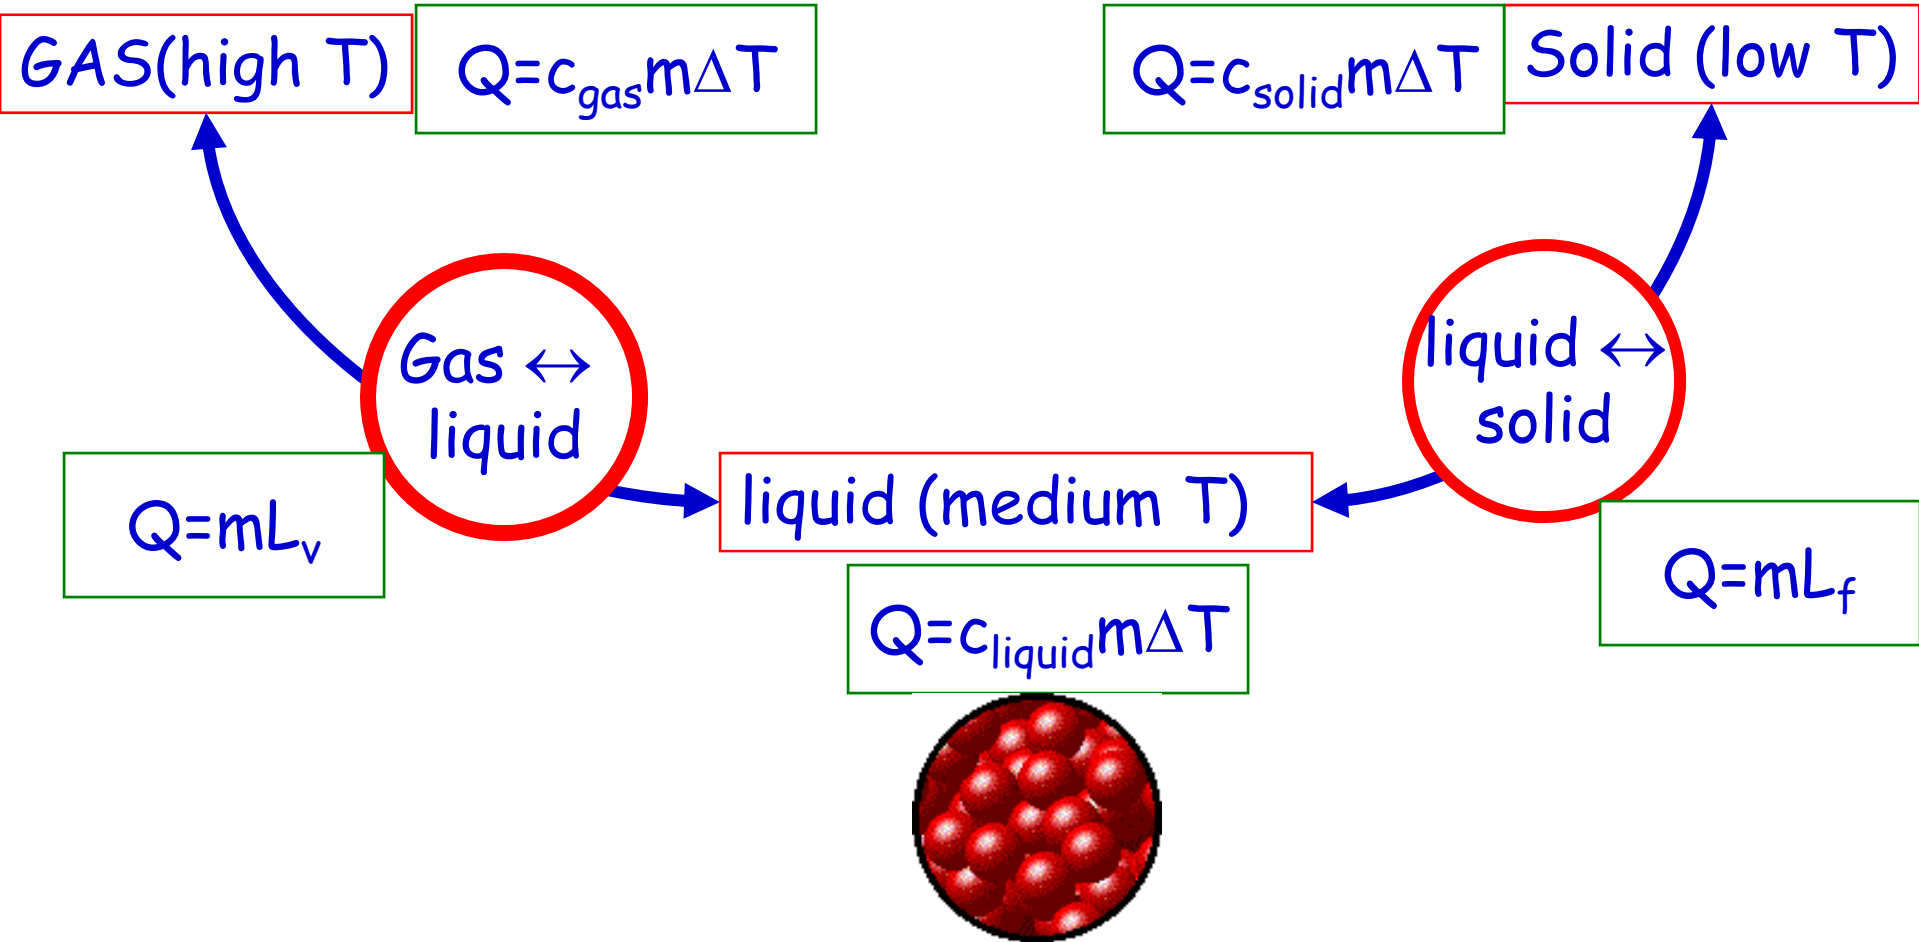

L_v = latent heat of vaporization (J/kg or cal/g)
depends on material.

$$Q_{\text{liquid} \rightarrow \text{solid}} = -ML_f \quad M: \text{mass}$$
$$Q_{\text{solid} \rightarrow \text{liquid}} = +ML_f$$

L_f = latent heat of fusion (J/kg or cal/g)
depends on material.

Phase Change

Example: Heating of H₂O

- | | | | |
|-----|----------------------|----------------------------|-------------------|
| (a) | <i>ice</i> | $Q = m c_{ice} \Delta T$ | raises T of ice |
| (b) | <i>ice+water</i> | $Q = m L_f$ | melts ice |
| (c) | <i>water</i> | $Q = m c_{water} \Delta T$ | raises T of water |
| (d) | <i>water + steam</i> | $Q = m L_v$ | vaporizes water |
| (e) | <i>steam</i> | $Q = m c_{steam} \Delta T$ | raises T of steam |

Example: Heating of H₂O

Ice with $T = -30\text{ }^{\circ}\text{C}$ is heated to steam of $T = 150\text{ }^{\circ}\text{C}$.

How much heat (in cal) has been added in total?

$$c_{\text{ice}} = 0.5\text{ cal/g }^{\circ}\text{C}$$

$$c_{\text{water}} = 1.0\text{ cal/g }^{\circ}\text{C}$$

$$c_{\text{steam}} = 0.480\text{ cal/g }^{\circ}\text{C}$$

$$L_f = 540\text{ cal/g}$$

$$L_v = 79.7\text{ cal/g}$$

$$m = 1\text{ kg} = 1000\text{g}$$

$$Q = 1000 * 0.5 * 30 = 15000\text{ cal}$$

$$Q = 1000 * 540 = 540000\text{ cal}$$

$$Q = 1000 * 1.0 * 100 = 100000\text{ cal}$$

$$Q = 1000 * 79.7 = 79700\text{ cal}$$

$$Q = 1000 * 0.48 * 50 = 24000\text{ cal}$$

$$Q = \underline{\underline{758700\text{ cal}}}$$

- | | | |
|-------------------|-----------------------------------|-------------------|
| (a) ice | $Q = m c_{\text{ice}} \Delta T$ | raises T of ice |
| (b) ice+water | $Q = m L_f$ | melts ice |
| (c) water | $Q = m c_{\text{water}} \Delta T$ | raises T of water |
| (d) water + steam | $Q = m L_v$ | vaporizes water |
| (e) steam | $Q = m c_{\text{steam}} \Delta T$ | raises T of steam |

A) Ice from -30 to $0\text{ }^{\circ}\text{C}$

B) Ice to water

C) water from $0\text{ }^{\circ}\text{C}$ to $100\text{ }^{\circ}\text{C}$

D) water to steam

E) steam from $100\text{ }^{\circ}\text{C}$ to $150\text{ }^{\circ}\text{C}$

Thermal conduction

ISOLATION

Previously: Phase Change

Example: Heating of H₂O

- | | | | |
|-----|----------------------|----------------------------|-------------------|
| (a) | <i>ice</i> | $Q = m c_{ice} \Delta T$ | raises T of ice |
| (b) | <i>ice+water</i> | $Q = m L_f$ | melts ice |
| (c) | <i>water</i> | $Q = m c_{water} \Delta T$ | raises T of water |
| (d) | <i>water + steam</i> | $Q = m L_v$ | vaporizes water |
| (e) | <i>steam</i> | $Q = m c_{steam} \Delta T$ | raises T of steam |

How can heat be transferred?

CONVECTION

RADIATION

Conduction

Touching different materials: Some feel cold, others feel warm, but all are at the same temperature...

Thermal conductivity

metal

$T=20\text{ }^{\circ}\text{C}$

$T=37\text{ }^{\circ}\text{C}$

The heat transfer
in the metal is
much faster than
in the wood:
(thermal
conductivity)

wood

$T=20\text{ }^{\circ}\text{C}$

$T=37\text{ }^{\circ}\text{C}$

Heat transfer via conduction

Conduction occurs if there is a temperature difference between two parts of a conducting medium

Rate of energy transfer P

$P = Q/\Delta t$ (unit Watt)

$$P = kA(T_h - T_c)/\Delta x = kA\Delta T/\Delta x$$

k : thermal conductivity

Unit: $J/(m \cdot s \cdot ^\circ C)$

metal $k \sim 300 J/(m \cdot s \cdot ^\circ C)$

gases $k \sim 0.1 J/(m \cdot s \cdot ^\circ C)$

nonmetals $\sim 1 J/(m \cdot s \cdot ^\circ C)$

Example

A glass window ($A=4 \text{ m}^2, \Delta x=0.5 \text{ cm}$) separates a living room ($T=20 \text{ }^\circ\text{C}$) from the outside ($T=0 \text{ }^\circ\text{C}$). A) What is the rate of heat transfer through the window ($k_{\text{glass}}=0.84 \text{ J}/(\text{m}\cdot\text{s}\cdot^\circ\text{C})$)? B) By what fraction does it change if the surface becomes 2x smaller and the temperature drops to $-20 \text{ }^\circ\text{C}$?

A) $P = kA\Delta T / \Delta x = 0.84 * 4 * 20 / 0.005 = 13440 \text{ Watt}$

B) $P_{\text{orig}} = kA\Delta T / \Delta x$ $P_{\text{new}} = k(0.5A)(2\Delta T) / \Delta x = P_{\text{orig}}$

The heat transfer is the same

Another one.

An insulated gold wire (i.e. no heat lost to the air) is at one end connected to a heat reservoir ($T=100\text{ }^{\circ}\text{C}$) and at the other end connected to a heat sink ($T=20\text{ }^{\circ}\text{C}$). If its length is 1m and $P=200\text{ W}$ what is its cross section (A)?

$$k_{\text{gold}}=314\text{ J}/(\text{m}\cdot\text{s}\cdot^{\circ}\text{C}).$$

$$P=kA\Delta T/\Delta x=314*A*80/1=25120*A=200$$

$$A=8.0\text{E}-03\text{ m}^2$$

And another
 $A=0.03 \text{ m}^2$ thickness: 0.5 cm.

A student working for his exam feels hungry and starts boiling water (0.5L) for some noodles. He leaves the kitchen when the water just boils. The stove's temperature is 150 °C. The pan's bottom has dimensions given above. Working hard on the exam, he only comes back after half an hour. Is there still water in the pan? ($L_v=540 \text{ cal/g}$, $k_{\text{pan}}=1 \text{ cal}/(\text{m}\cdot\text{s}\cdot^\circ\text{C})$)

To boil away 0.5L (=500 g) of water: $Q=L_v \cdot 500=270000 \text{ cal}$
 Heat added by the stove: $P=kA\Delta T/\Delta x=1 \cdot 0.03 \cdot 50/0.005=$
 $=300 \text{ cal}$

$P=Q/\Delta t$ $\Delta t=Q/P=270000/300=900 \text{ s}$ (15 minutes)

He'll be hungry for a bit longer...

Isolation

$$P = \frac{Q}{\Delta t} = \frac{A(T_h - T_c)}{\sum_i (L_i / k_i)}$$

T_h inside

L_1 L_2 L_3

A house is built with 10 cm thick wooden walls and roofs. The owner decides to install insulation. After installation the walls and roof are 4 cm wood+2 cm isolation+4 cm wood. If $k_{\text{wood}}=0.10 \text{ J}/(\text{m}\cdot\text{s}\cdot^\circ\text{C})$ and $k_{\text{isolation}}=0.02 \text{ J}/(\text{m}\cdot\text{s}\cdot^\circ\text{C})$, by what factor does he reduce his heating bill?

$$P_{\text{before}} = A\Delta T / [0.10/0.10] = A\Delta T$$

$$P_{\text{after}} = A\Delta T / [0.04/0.10 + 0.02/0.02 + 0.04/0.10] = 0.55A\Delta T$$

Almost a factor of 2 (1.81)!
